- Russian River Health Center (707) 869-2849
- Kaiser Permanente (707) 393-4044

Respiratory Syncytial Virus (RSV)

Each year in the United States, RSV kills up to 10,000 people, including 100 to 300 children. The CDC estimates that 1 or 2 of every 100 children will be hospitalized with a lower respiratory tract infection caused by RSV in the first six months of life, and virtually all children are infected with RSV at least once by the time they are 24 months of age. On the other end of the spectrum, most of those who die from RSV infections are the elderly.

In 2023, tools for preventing RSV became available for two of the most susceptible age groups — infants and the elderly. For the elderly, the new tool is a traditional vaccine; however, for infants, the tool is not a vaccine. It is a monoclonal antibody. This means that infants will get antibodies that last long enough to protect them during their first and most susceptible RSV season, but the antibodies will fade, and eventually, the babies will be exposed to RSV and make their own immune response at a time when they are less susceptible to severe disease.

Other prevention measures include: Limiting the number of people that are around your baby, particularly during the first several months of life and during winter virus season. Having people wash their hands and refrain from kissing or touching the baby on or around their face. If someone has cold-like symptoms, asking them to refrain from visiting with your baby until they have recovered.

El Virus Respiratorio Sincitial (VRS)

Cada año en los Estados Unidos, el VRS mata hasta 10,000 personas, incluyendo de 100 a 300 niños. CDC estima que 1 o 2 de cada 100 niños serán hospitalizados con una infección del tracto respiratorio inferior causada por el VRS en los primeros seis meses de vida, y prácticamente todos los niños se infectan con el VRS al menos una vez antes de los 24 meses de edad. En el otro extremo del espectro, la mayoría de los que mueren por infecciones por VRS son los ancianos.

En 2023, la ayuda para prevenir el VRS estuvo disponible para dos de los grupos de edad más susceptibles: los bebés y los ancianos. Para las personas mayores, la nueva ayuda es una vacuna tradicional; Sin embargo, para los bebés, la ayuda no es una vacuna. Es un anticuerpo monoclonal. Esto significa que los bebés obtendrán anticuerpos que durarán lo suficiente como para protegerlos durante su primera y más susceptible temporada de VRS, pero los anticuerpos se desvanecerán, y finalmente, los bebés estarán expuestos al VRS y producirán su propia respuesta inmunitaria en un momento en que son menos susceptibles a la enfermedad grave.

Otras medidas de prevención incluyen: Limitar el número de personas que están cerca de su bebé, especialmente durante los primeros meses de vida y durante la temporada invernal del virus. Hacer que las personas se laven las manos y se abstengan de besar o tocar al bebé en o alrededor de la cara. Si alguien tiene síntomas similares a los de un resfriado, pídale que se abstenga de visitar a su bebé hasta que se haya recuperado.
